Week 2:

1-) First problem we encountered during the parsing information from txt is the types. So, we must convert type string to necessary format such as string to int, string to datetime format. We solved them by using python functionalities.

2-) Second issue was, the format of the parsed string didn't fit into our database. Like the name was "Firstname Secondname". But in our table firstname and second name are two distinct columns. So we must divide the names and then assign them to columns:

3-) Some entity type from txt file correspond to only one entity in our database. Like vendors and NPC's are concatenated in our database.

4-)There were some columns left as null after parsing. We insert random values to those null values. That part is made simultaneouslt with week 3. So every column of every table was filled. Mostly random method was used. Sometimes we created a small population on our own and then randomly populated it.
